

PROGRESS REPORT & PRELIMINARY DATA:

Qualitative comparison of aquatic habitats and fish species diversity, today and 50 years ago, in the Platte and North Platte rivers of Nebraska

Principal Investigator:

Beth Goldowitz

Platte River Whooping Crane Maintenance Trust, Inc.

The Platte River Trust is studying temporal changes in the aquatic habitats and fish species composition of the Platte and North Platte rivers in Nebraska. More than 50 years ago, Johnson conducted a study of the distribution of fishes in Nebraska.¹ The Trust has returned to sites sampled by Johnson and has repeated fish collections there. For both fish species and aquatic habitats, we are comparing our data, reflecting current conditions, with Johnson's historic information.

For the habitats, we are comparing both qualitative descriptions and photographic records of the sites in this study. For the fish fauna, we are examining changes in species diversity and species composition at the selected sites. Johnson sampled fish by seining; the Trust has combined seining with electroshocking in its sampling.

Between 1992 and 1994, the Trust revisited and sampled six of Johnson's sites on the North Platte and Platte rivers between Sutherland and Grand Island. At three of those sites, we have also conducted sampling repeatedly in successive years.

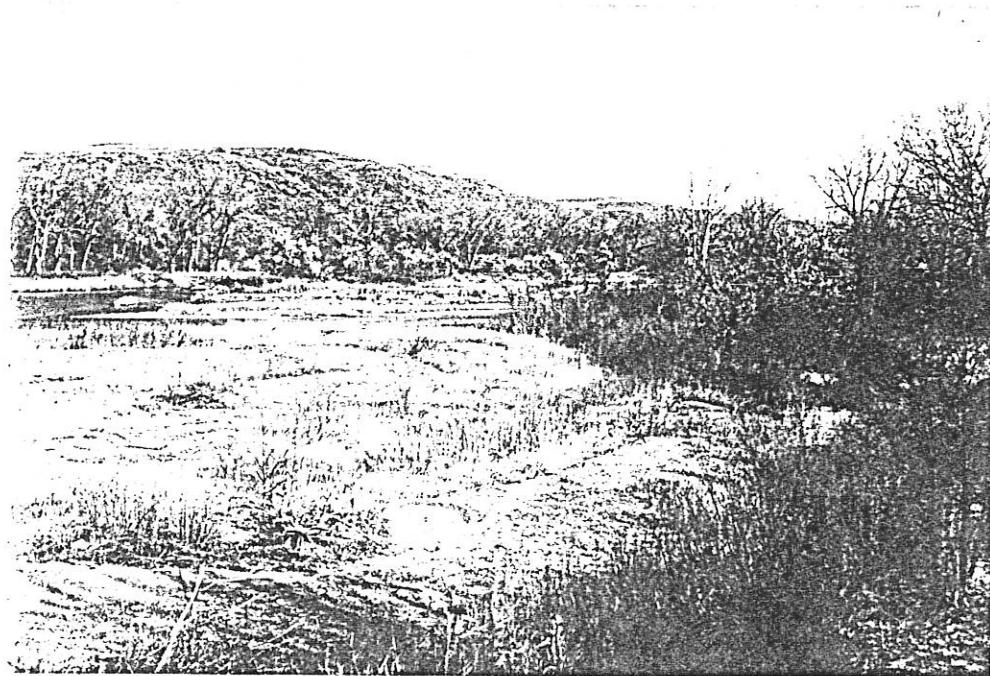

The most dramatic changes in the riverine habitat have occurred at the westernmost sites, between Sutherland and Lexington. Further downstream, from Kearney to Grand Island, the habitat retains more of its historic character (Figures 1 and 2).

Fish species composition has apparently changed at all the study sites (Tables 1-6). Some changes are due to introductions of exotic species that have occurred since Johnson's study (e.g., western mosquitofish and brook silverside at the Grand Island site; Table 5). In other cases, species have disappeared from the Trust's more recent collections (e.g., all the *Hybognathus* and *Carpoides* species at the Lexington site; Table 3).

Species richness declined at the three most upstream study sites, between Sutherland and Lexington (Tables 1-3). Richness increased at one site (Kearney; Table 4) and remained constant at two sites (near Grand Island; Tables 5-6). The most dramatic change occurred at Lexington, where species richness in the Trust's sample was only 59% of what Johnson found (10 versus 17 species; Table 3).
